To: Board of Directors  
Aquarius Condominium Association, Inc.  
2751 South Ocean Drive  
Hollywood, FL 33019

Re: Building Damage Survey Report

**ABSTRACT:**

As per the Board's request, a damage survey of Aquarius Condominium buildings balconies, columns, beams and walls was accomplished during the months of August and September, 2014. The purpose of the survey was to determine the levels of damage to the balconies, wall structures, columns and beams and to help determine a repair strategy and budgetary cost estimate, for a forty year recertification of the buildings. Examinations were accomplished primarily visually and by acoustic soundings.

Please keep in mind that estimating these types of projects is not an exact science. The size, complexity, and numerous variables that affect costs on these repair projects means Board Members and Owners will have many questions as you review our findings. We look forward to addressing your concerns, encourage you to make notes as you review the data and bring your questions to our attention during our planned meetings. We would recommend a "working" meeting be held in person with the Board as soon as possible after receiving the report. Over the next few weeks we will work with the Board to assure you understand our findings, explore your options, and begin to develop a plan by which the problems can be addressed as budgets allow.

**CHLORIDE RELATED DAMAGE:**

The primary mechanism for corrosion damage at the Aquarius Condominium is that of chloride based corrosion. Corrosion of reinforcement steel in concrete structures is a recurring and expensive form of damage prevalent along Florida's coastlines. The problem arises due to a combination of chlorides, moisture, and warm temperatures.

Initially, when reinforced concrete structures are first constructed, the presence of minor surface rust on the steel is a common occurrence. This minor covering of surface rust does not present a problem to the building, however, because within weeks the corrosion is arrested by formation of a passivation layer on the steel's surface. This occurs due to a

chemical reaction between the alkali concrete (pH 13-14) and the steel. Corrosion is therefore arrested and the situation would remain such except for the presence of two primary mechanisms for change – sea salt and carbon oxides in the atmosphere.

The presence of chlorides in the form of salt is the primary mechanism that eventually leads to damage for most of the buildings we examine along the coast. Studies have shown that approximately 0.1 to 0.2 lbs. of chlorides, per square foot, deposit on building surfaces each year along the coastline. As the chlorides fall onto the decks, columns and beams, and are soaked into them by rains, they begin to accumulate in the porous concrete. When the level of chlorides reaches a threshold level of 1.25 to 1.50 lbs. / cubic yard in the concrete near the steel, the passivation layer breaks down and the steel begins to corrode again. The threshold value usually occurs within 8 to 12 years along our coastline for unprotected concrete.

Once initiated, the rate of corrosion will depend on the amount of moisture present and how much alternate drying and wetting occurs. In general, Florida's high humidity means sufficient moisture is always prevalent. Warm ambient temperatures also assist in maintaining corrosion levels. Left untreated, corrosion will continue to such a point that the steel is completely destroyed and the building's structural integrity is severely diminished.

Other factors which affect how quickly the chlorides reach the steel are the amount of concrete covering the steel and the density of the concrete. The water-cement ratio of the concrete mix is a big driver in affecting permeability and thus absorption rates. More water means the concrete has less strength and is more porous.

Once begun, corrosion tends to accelerate with time. As the steel corrodes, the rust, which forms on the surface of the steel, creates pressures within the concrete surrounding it because rust occupies 4 to 7 times the equivalent volume of steel. These resulting pressures eventually cause the concrete to crack. If the cracks are near the surface and occur in a plane parallel to such, chunks of concrete are loosened (spalls). The cracks allow more moisture to intrude, accelerating the corrosion rate. These cracks will usually occur 3 to 5 years after the threshold level has been reached – meaning we first observe cracking of structures at about 15 to 18 years of age, given common conditions.

The other mechanism encountered to a lesser extent is that of carbonation, briefly mentioned above. Carbonation is the reaction of concrete with carbon oxides in the atmosphere, causing the concrete to become more acidic (lowering the pH). This mechanism is much slower and is not the prevalent mechanism on balconies and walkways. It tends to show up more in much older structures and especially in garage structures.

#### **REPAIR METHODS:**

The generally accepted method of repair is to remove the concrete surrounding the corroded steel, abrasively clean the steel, coat it with a corrosion-resistant material, replace the concrete, and apply a waterproofing membrane to the surface. Abrasively cleaning the steel (sand blasting) is extremely important to remove chlorides, which may be present in deeply corroded steel. Corroded steel in excess of a 15% cross-section loss requires that new steel be spliced into the structure. Repair mortars are specifically chosen to have low shrinkage and match the existing concrete. Water content is held to 0.40 water/cement ratios to provide dense, less permeable concrete. In addition, corrosion inhibitors such as WR Grace's DCI are added to the new mortar to resist chlorides for as long as 35 years. Finally, we recommend a waterproofing membrane, either urethane or cementitious, be applied over the entire deck to keep water out. The above recommendations are accepted standards of the American Concrete Repair Institute.

#### **SPECIFIC FINDINGS:**

The following summary details concrete damage as well as other observations. Generally, observations are summarized as follows:

- Both buildings present significant edge repair. We could observe that the majority of the balconies have been previously repaired.
- The majority of the balconies are tiled, although some of them are on bare concrete and show similar soundings around the door areas showing signs of concrete deterioration. Some of these repairs could eventually finish with sliding glass door removals and weather wall installations.
- We could observed a good amount of rust spots on the ceilings and in some cases these areas have become overhead spallings. Some of these repairs if aligned with the partial repairs on the balconies above could become thru deck repairs.

#### **COST ESTIMATES:**

Because of the complexities in determining the exact amount of damage and corrosion present, variables in construction quality, concrete quality, and environmental conditions, it is in essence impossible to exactly calculate the cost repairs for restoration projects. For this reason, most contractors will not consider a project of this type on a fixed price basis and if they do, the price is usually very high. Instead, repairs are accomplished on a unit price basis, meaning the owners pay for the repairs based on the amount of repairs

necessary. The engineer determines how much repair is necessary, and acts as the owner's agent to assure the contractor only repairs and is paid for repairing that amount. Theoretically, given the same unit price, the choice of contractor should not change the cost of the project.

Finally, we know there are also unknowns for most projects – things we did not anticipate changes and change orders the owners may request, complications not expected and even mistakes in our estimates. Most of the time, our experience says our projects come in plus or minus 30% of our median estimate. However, we recommend the Board in this case a 20% contingency. This value is also shown as a recommended budget value.

#### **CONCLUSIONS:**

The levels of damage on the building are consistent with the age and location of the building. Owners have expended some resources to maintain the structural integrity of the building. However, corrosion of reinforcement steel has caused substantial damage never the less.

Many of the damaged areas we documented are primarily on the edges and the interior areas of the balconies. Some of the repairs will require partial repairs near the sliding glass doors, in most cases intrusion to the units will be required.

The stucco of the walls shows signs that is either delaminated or crack and should be replaced to prevent water intrusion.

#### **RECOMMENDATIONS:**

The Board should consider initiating a repair project to address as many of the repairs as can be afforded. Should money not be available in reserve, or by assessment, consideration should be given to borrowing money, since rates are currently very attractive.

These repairs address the immediate damage and are aimed at taking preventive measures to slow the rates of corrosion. However, it is important to understand that chloride and carbonation damage will continue and additional repairs will be needed, as the structures get older. Once repairs are complete, a reserve analysis and future maintenance plan should be completed to minimize the future repair cost and lessen the impact to the owners.

Based on the limits of the typical work schedule and large cost of the project, it is recommended to consider segmenting the repairs. Priorities can address based on relative damage by building stacks or other parameters depending on the Board's desires.

Please call me should you have any questions or require further clarification.

Respectfully,

Andres Caicedo  
President
